ABSTRACT

A door lock device can be surely unfastened under a condition where a high lateral pressure is applied to a swing door. A includes a latch 2 is provided in a door 1-so as to project from the side surface 1a of the door 1, and a hook 6 is supported opposite to the latch 2 in a doorjamb 3. The such that the hook 6 can turn between a latch detaining position and a latch releasing position. A hook control member 7 has a shaft 7a having a middle part 7e with a semicircular cross section, and a lever 7b extending perpendicularly to the shaft. The hook control member 7 turns between a hook detaining position at a locking position and a hook releasing position. First, second and third rocking plates 15, 21 and 24 are interlocked with the hook control member 7. When a solenoid actuator rod 36 engaging with the third rocking plate 24 projects upward to fasten the door lock device, the third rocking plate 24 is turned clockwise by the a pin 38, and the second rocking plate 21 having a pin 21a pressed against the third rocking plate 24 turns clockwise. Consequently, an upper part 21b of the second rocking plate 21 comes into contact with a projections-15b of the first rocking plates-15 to restrain the first rocking plates 15 from clockwise turning, and a roller 17 supported on the first rocking plates 15 engages with a lever 7b of the hook control member 7-to detain the hook control member 7 at a hook detaining position for detaining the hook θ at the locking position. When the rod θ is retracted to unfasten the door lock device, the second and third rocking plates 1 and 24 are turned counterclockwise by springs pressing the same counterclockwise. When the second rocking plate 21 is thus turned, the upper part 21b exerts an impact on a second projections 15c formed in a lower parts of the first rocking plate 15. Thus, the first rocking plate 15 can be turned clockwise by the impulse to enable the hook control member 7 to turn to the hook releasing position even if the lever 7b is pressed against the roller 17 by a high lateral presser P working on the swing door 4 against a frictional resistance exerted by the lever 7b on the roller 47.
